

**Week 9 problem solving**  
*+ equations, + applications*

**Kinetics, diffusion, dissolution**

# Dissolution rate of drug crystals

- The Rate is proportional to the **total surface area** of drug *micro-crystals*
- *Individual area per mass depends on Crystal **habit** (shape)*
- **Cubes** have the **smallest surface area** per given volume
  - lowest dissolution rate
- Breaking the same amount of substance into **smaller particles** increases the total surface area,
- For **cubes**: **Total\_Area = Total\_Volume/OneCubeEdgeLength**
  - Increased dissolution rate for smaller ones
  - For arbitrary shape micro-crystals:
    - Calculate surface **a**rea and volume of each microcrystal (**v**)
    - Divide the fixed total Volume by the single-crystal volume
      - $N = V_{tot}/v$
    - Multiply the **Total\_Area = a\*N**
    - Dissolution rate is proportional to the total surface area

# Dissolution rate of crystals

- **Q:** Three formulations are used to deliver **equal amounts** of the same drug.
  - ❖ Formulation **X** consists of cubic microcrystals of size  $1\mu\text{m} \times 1\mu\text{m} \times 1\mu\text{m}$
  - ❖ Formulation **Y** features cubic microcrystals of size  $0.1\mu\text{m} \times 0.1\mu\text{m} \times 0.1\mu\text{m}$
  - ❖ Formulation **Z** contains needle-like, elongated microcrystals of size  $100\mu\text{m} \times 0.1\mu\text{m} \times 0.1\mu\text{m}$
- Rank the formulations in the order of increasing dissolution rate:
  - X < Y < Z
  - X < Z < Y
  - Y < X < Z
  - Y < Z < X
  - Z < Y < X
  - Z < X < Y

- **Solution:**

	X	Y	Z
<b>Xtal dimensions</b>	$1\mu\text{m} \times 1\mu\text{m} \times 1\mu\text{m}$	$0.1\mu\text{m} \times 0.1\mu\text{m} \times 0.1\mu\text{m}$	$100\mu\text{m} \times 0.1\mu\text{m} \times 0.1\mu\text{m}$
<b>Volume per xtal</b>	$V$	$0.001 \times V$	$V$
<b>SA per xtal</b>	$A = 6\mu\text{m}^2$	$0.01 \times A$	$\approx 40\mu\text{m}^2 \approx 6.66 \times A$
<b># of xtals</b>	$N$	$1000 \times N$	$N$
<b>Total SA</b>	$A \times N$	$10 \times A \times N$	$\approx 6.66 A \times N$

- **Answer:** X < Z < Y

# Drug absorption in the GI tract

- Let us make the following assumptions:  
The surface area of the stomach is  $\sim 0.1 \text{ m}^2$  and that of the intestine is  $\sim 100 \text{ m}^2$ .  
The pH in the stomach and the intestine is 2 and 7, respectively (simplification)
- Q:** An acidic drug with the  $pK_A$  of **4** is taken orally, dissolves in the stomach and spends  $\sim 1 \text{ hr}$  in the stomach and  $\sim 4 \text{ hrs}$  in the intestine as it moves through the GI tract. What percentage of the drug is absorbed in the stomach? What percentage is absorbed in the gut?
- Hint:** *only neutral drug species are absorbed efficiently*
  - 100% in the stomach, negligible in the gut
  - 80% in the stomach, 20% in the gut
  - 50/50
  - 80% in the gut, 20% in the stomach
  - 100% in the gut, negligible in the stomach

- Solution:**

	$10^{pK_a-pH}$	Fraction neutral	Time	Area	Total absorbed assuming flux $J$
Stomach	$10^{4-2} = 100$	$\sim 1$	1 hr	$0.1 \text{ m}^2$	$J \times 1 \times 1 \times 0.1 = 0.1 J$
Intestine	$10^{4-7} = 0.001$	$\sim 0.001$	4 hrs	$100 \text{ m}^2$	$J \times 0.001 \times 4 \times 100 = 0.4 J$

- Answer:** 80% in the gut, 20% in the stomach

# Rates of reactions, K

	0 <sup>th</sup> order	1 <sup>st</sup> order	2 <sup>nd</sup> order
Rate law ( <i>how fast?</i> )	Fixed time	Exponential decline	
Integrated rate law ( <i>extent of the reaction after the given time elapsed</i> )	$[A] = [A]_0 - k_0 t$	$[A] = [A]_0 e^{-kt}$	
Units of $k$	M s <sup>-1</sup>	s <sup>-1</sup>	M <sup>-1</sup> s <sup>-1</sup>
Half-life $t_{1/2}$	$t_{1/2} = A_0 / 2k_0$	$t_{1/2} = \ln(2)/k$	
Examples	Degradation, dissolution at infinite dilution	Elimination, isomer conversion, radioactive decay	1:1 protein-ligand binding

# Reaction rate: 1<sup>st</sup> order

- **Q:** Thalidomide undergoes spontaneous conversion from (+) form to (-) form and vice-versa. For example, the half-life of initially pure (+)Thalidomide in human plasma is 11.5 minutes. Estimate the **rate constant** for the reaction of conversion of (+)Thalidomide into (-)Thalidomide in human plasma.
- **Hints:**
  - Enantiomer conversion is 1st order; hence constant  $t_{1/2}$
  - Asks for rate constant ( $k$ ), not rate ( $d[A]/dt = -k[A]$ )
- A.  $11.5 \text{ min}^{-1}$
- B.  $8.33 \text{ min}^{-1}$
- C.  $0.001 \text{ s}^{-1}$
- D.  $\ln 2 \text{ s}^{-1}$
- **Solution:**
  - $t_{1/2} = 11.5 \text{ min} = 690 \text{ s}$
  - The rate constant is  $k = \ln 2 / t_{1/2} = \ln 2 / 690 \sim 0.001 \text{ s}^{-1}$
- **A:**  $0.001 \text{ s}^{-1}$

# Reaction rate etc.: 1<sup>st</sup> order

- **Q:** Iodine-131 decays with the half life of 8 days. At the time of calibration, the activity in the vial is 100 mCi. What will be the remaining activity after 32 days?

- A. 96 mCi
- B. 31.25 mCi
- C. 25 mCi
- D. 6.25 mCi

**Ci** is a **Curie** unit of radiation

It is  $3.7 \times 10^{10}$  Bq (disintegrations or nuclear transformations per second).

A Ci is emitted by 1 g of radium-226.

- **Solution 1:**

- The rate constant is  $k = \ln 2 / t_{1/2} = \ln 2 / 8 \text{ days} = 0.0866 \text{ d}^{-1}$
- $[A] = [A]_0 e^{-kt} = 100 \text{ mCi} \times e^{-2.7726} = 100 \text{ mCi} \times 0.0625 = 6.25 \text{ mCi}$

- **Solution 2:**

- After 8 days, the remaining activity will be 50 mCi
- After 16 days, 25 mCi
- After 24 days, 12.5 mCi
- After 32 days, 6.25 mCi
- **A:** 6.25 mCi

# Rates vs equilibrium in reversible reactions

- In a reversible reaction, two rates:
  - One for **forward** reaction:  $k_f$
  - Another for **reverse** reaction:  $k_r$
  - Two half-lives depending where one starts
- At equilibrium,  $[A]k_f = [B]k_r$

$$K_{eq} = \frac{k_f}{k_r}$$

- A bimolecular reaction of drug-target binding:
  - $k_f = k_{on}$  (kinetic association constant, not to be confused with equilibrium association constant)
  - $k_r = k_{off}$  (kinetic dissociation constant, not to be confused with equilibrium dissociation constant)

Equilibrium dissociation constant  $K_d = \frac{k_{off}}{k_{on}}$

Important parameter: drug **residence time**

$$\tau = \frac{1}{k_{off}}$$

# Equilibrium vs rates in a reversible 1<sup>st</sup> order reaction

- **Q:** The reversible reaction of drug A binding to its target is characterized by  $k_{on} = 8 \times 10^6 \text{ M}^{-1} \text{ min}^{-1}$  and the equilibrium dissociation constant  $K_d = 0.5 \text{ nM}$ . Find  $k_{off}$  and the drug residence time  $\tau$  at the target.

- A.  $k_{off} = 0.004 \text{ min}^{-1}$ ,  $\tau = 4 \text{ hr } 10 \text{ min}$
- B.  $k_{off} = 0.12 \text{ min}^{-1}$ ,  $\tau = 500 \text{ sec}$
- C.  $k_{off} = 1.6 \times 10^{16} \text{ min}^{-1}$ ,  $\tau = 6.25 \times 10^{-15} \text{ min}$
- D. Impossible to tell

- **Solution:** use  $K_d = \frac{k_{off}}{k_{on}}$  and  $\tau = \frac{1}{k_{off}}$

$$k_{off} = K_d \times k_{on} = (0.5 \times 10^{-9} \text{ M}) \times (8 \times 10^6 \text{ M}^{-1} \text{ min}^{-1}) = 4 \times 10^{-3} \text{ min}^{-1} = 0.004 \text{ min}^{-1}$$
$$\tau = 1/k_{off} = 1/0.004 = 250 \text{ min}$$

- **Answer:**

$$k_{off} = 0.004 \text{ min}^{-1}, \tau = 4 \text{ hr } 10 \text{ min}$$

This is a **long-residence-time** drug

Often a desirable feature in pharmacology: the target is inhibited for many hours after the dose, regardless of plasma concentration decrease
